Cytology of mediastinal lesions

ANDRE L. MOREIRA, MD, PHD

NEW YORK UNIVERSITY LANGONE HEALTH

Introduction

The mediastinum can be affected by a heterogeneous group of disease that can cause significant diagnostic difficulties.

Lesions of the mediastinum can be explored by fine-needle aspiration biopsy (FNAB) obtained under radiographic guidance, either through a transthoracic, esophageal or bronchoscopic approach

Aspiration biopsy of the mediastinum is rare
Imaging and clinical parameters are often diagnostic
Accuracy is approximately 85% for all mediastinal lesions
Aspiration biopsy of metastatic mediastinal tumors are
more common

Sensitivity and specificity

Varies with location within the mediastinum

- Anterior/pre-vascular = 80%/98%
- Posterior= 33%/95%
- Medial/vascular=100%

Varies for different classes of diseases

- •Thymoma = 87%/94%
- •Germ cell tumor= 100%/99%
- **Cyst=** 25%/100%

pattern recognition approach

- -6 identifiable patterns:
- -Spindle shaped cells (Thymoma Type A)
- -Lymphocyte-rich (Thymoma B1)
- -Epithelioid-rich (Thymoma B2 and B3)
- -Small blue cells
- -Inflammatory
- -Cystic
- -Each pattern carries a set of differential diagnosis.

Spindle shaped cells

Differential Diagnosis

Spindle-cell thymoma (W.H.O. type A)

Spindle-cell carcinoid tumor

Schwannoma (posterior mediastinum)

Sarcoma or soft tissue tumor

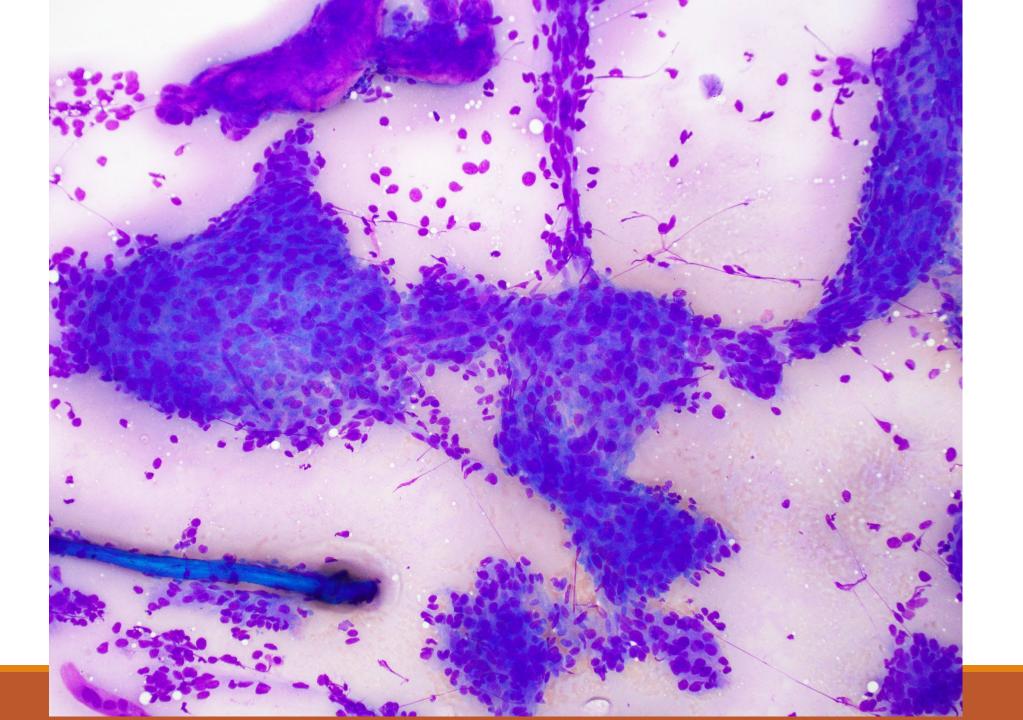

Mesenchymal component of teratoma

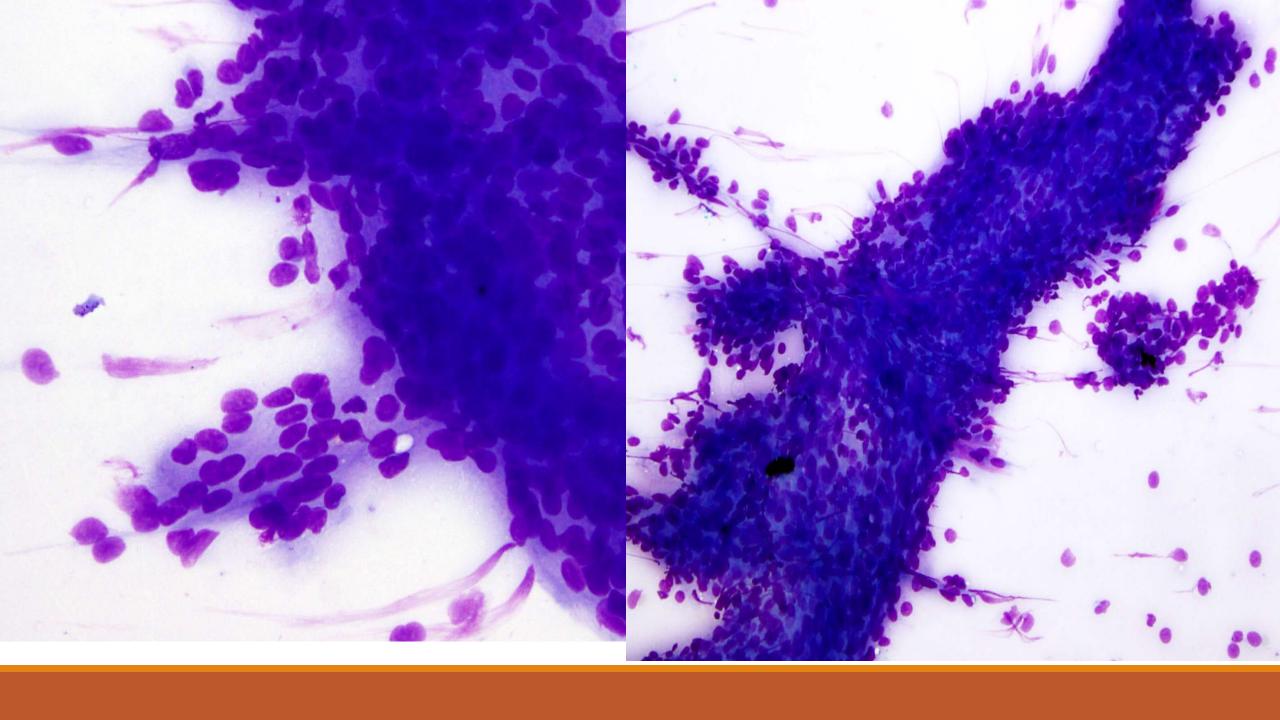

Case 1

44 year old man, former smoker with a 34 packs/year.

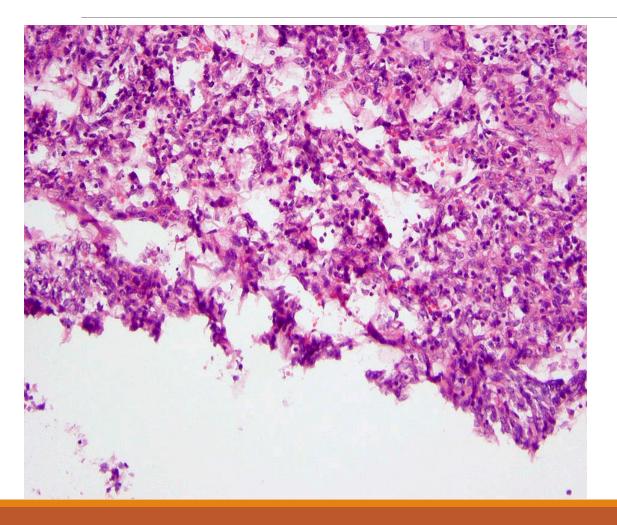

Presents with an anterior mediastinal mass, multiple pleural nodules and pleural effusion.

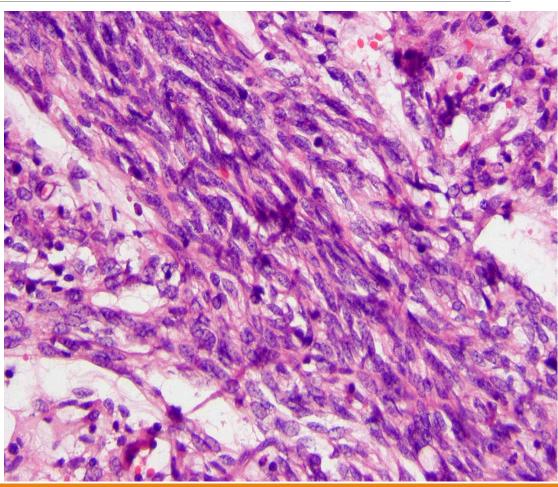

Aspiration biopsy of a pleural nodule was performed.

Cell block material

IHC

Positive for pan-cytokeratin and p63

Negative for WT-1, Calretinin, TTF-1, cytokeratin 7, neuroendocrine markers, CD34, STAT6, and other organ specific markers.

Thymoma type A

Cohesive tissue fragments.

Elongated cells embedded in a metachromatic matrix (Diff-Quick)

Presence of lymphocytes in the background

Absence of lymphocytes do not exclude the diagnosis

Thymoma type A

Tumor cells are positive for pan-cytokeratin

Can be positive for CD56 (but negative for other NE markers)

If present, lymphocytes are immature thymic lymphocytes (CD5, CD99, TdT positive)

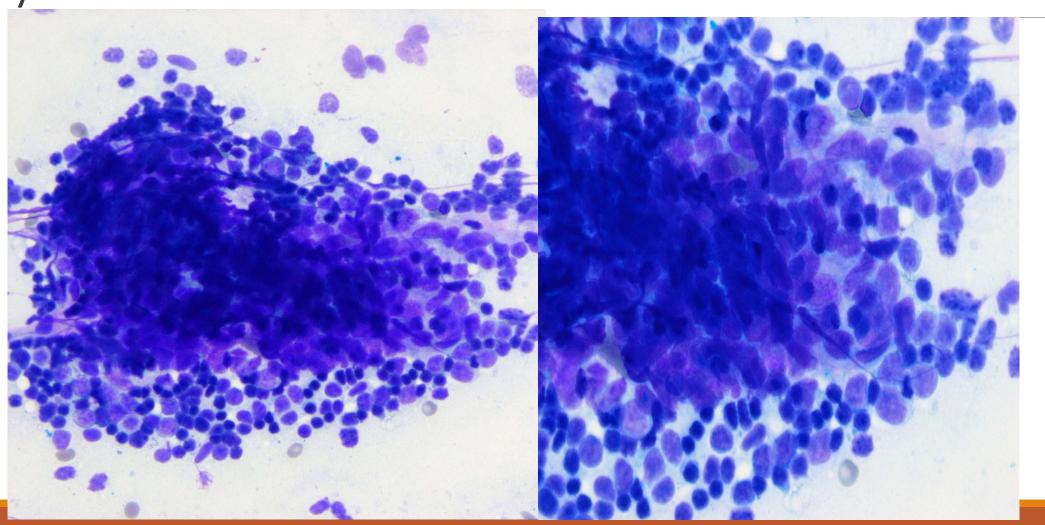

Lymphocyte-rich tumors

Lymphoma

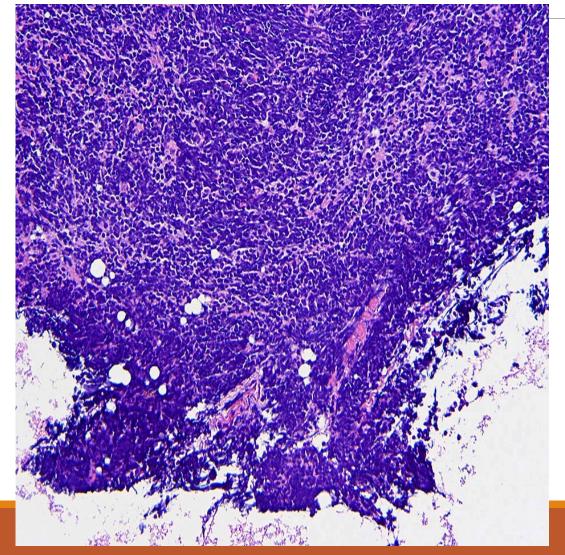

Thymoma (W.H.O. type B1)

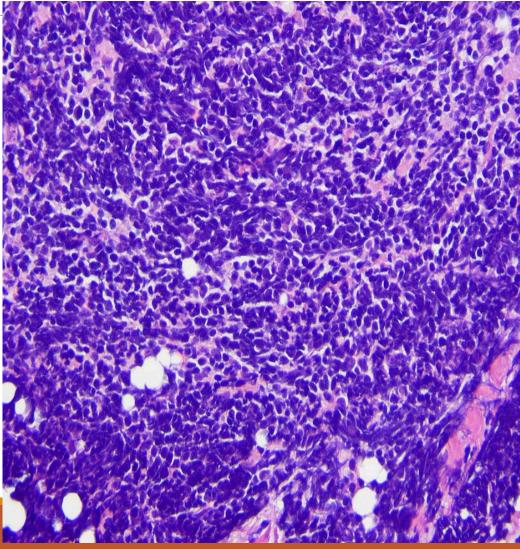

Thymic hyperplasia

Case 2 FNA of a mediastinal mass on a 78 year old man

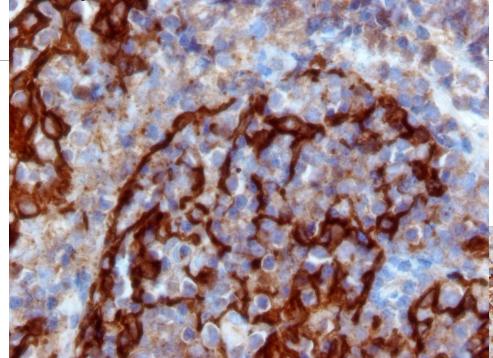

Excision

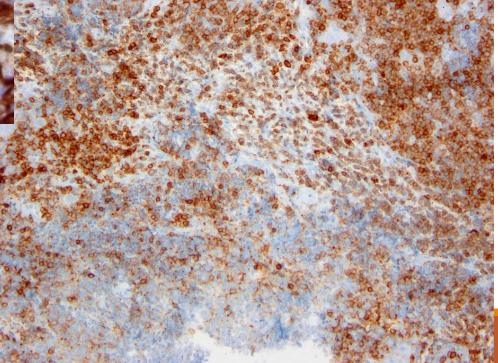

B1 Thymoma

Cytokeratin AE1/AE3

CD5

B1 thymoma

Predominance of heterogeneous lymphocytes

Small discrete clusters that resembles "lymphoid tangles" containing cells with open chromatin, nucleoli can be prominent or not

Flow cytometry shows a predominance of T lymphocytes

Immunohistochemical stains for keratin show a network of keratin positive cells, lymphocytes are immature T cells (CD3, CD5, CD4, CD8, TdT, CD99, CD1a positive)

Thymic Hyperplasia

Follicular hyperplasia is most common

Often associated with autoimmune disorder or history of chemotherapy

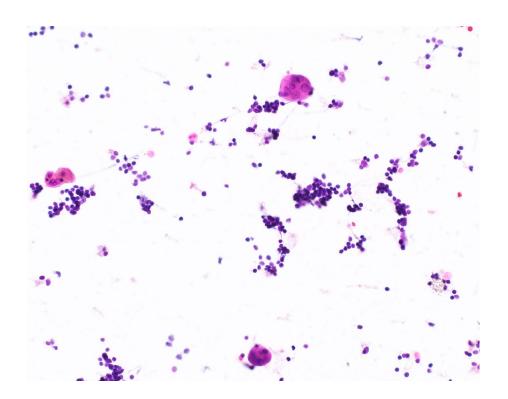

Can be very difficult to differentiate in an aspiration biopsy from a B1 Thymoma

MRI is the best pre-surgical test for the diagnosis

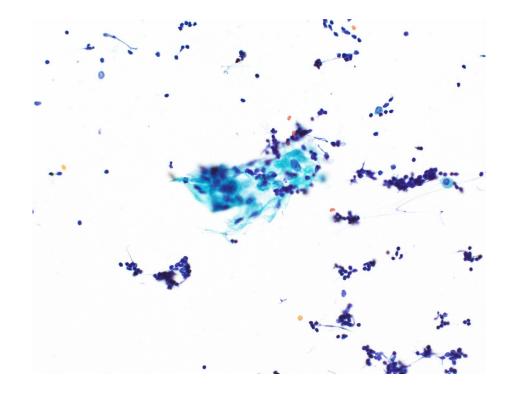

Often scant cellular smears, Hassall's corpuscles are easier to find, but are not specific

Thymic hyperplasia

HASSALL'S CORPUSCLES H&E

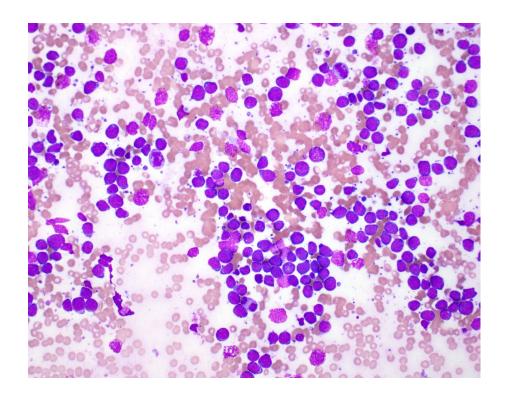

HASSALL'S CORPUSCLES PAP

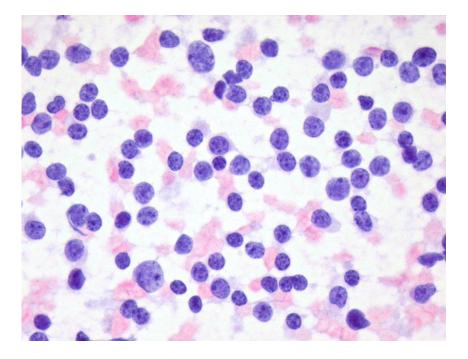

Lymphoma

LARGE B-CELL LYMPHOMA

ACUTE LYMPHOBLASTIC LYMPHOMA

Epithelioid-rich pattern

Metastatic carcinoma

Thymoma, type B2-B3

Thymic carcinoma

Carcinoid tumor

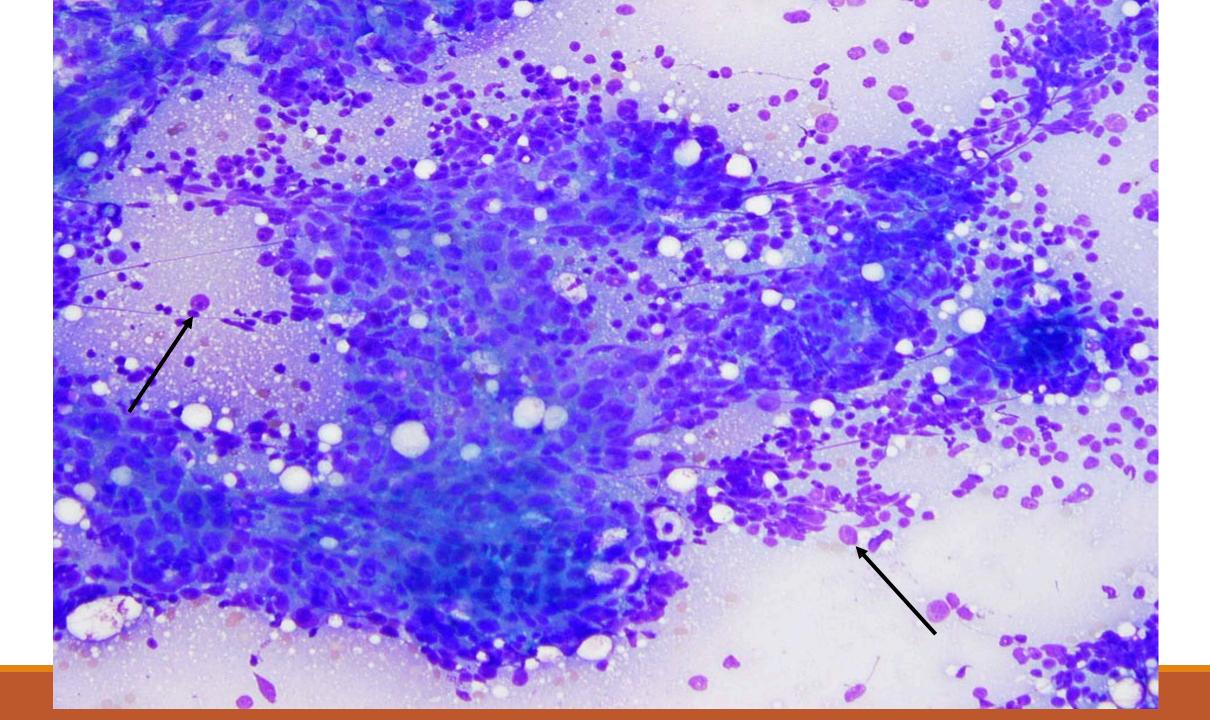

Germ cell tumor

Case 3

57 year old woman, presented with chronic cough.

A CT-Scan showed a large mediastinal mass with pericardial effusion

An aspiration biopsy of the mediastinal mass was performed

IHC work up

Thymoma- keratin and p40+, immature lymphocytes TdT +

Thymic carcinoma- keratin, p40, CD5, CD117+

Metastatic carcinoma and germ cell tumor- Clinical history and target IHC

Metastatic squamous cell carcinoma

FNA — Thymoma Type B2-B3

Moderate to highly cellular smears

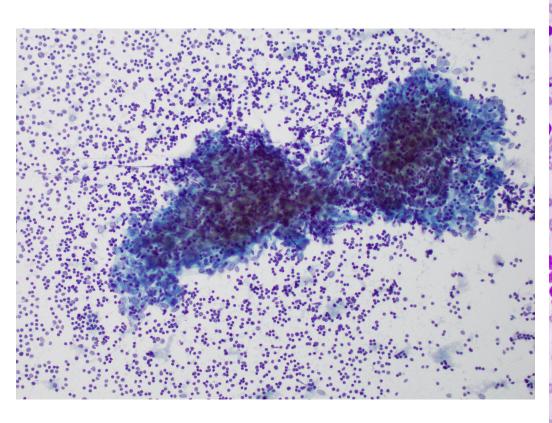

Duo population of epithelial and lymphoid cells (classical cytologic features)

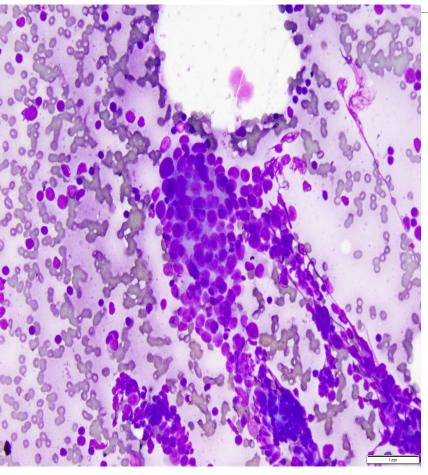

Epithelial arranged in cohesive tri-dimensional clusters

Open chromatin with delicate or prominent nucleoli

Can be confused with carcinoma!

Thymoma B2 and B3

Thymic carcinoma

Positivity for CD5 and CD117 in epithelial cells (40-60% of thymic carcinomas).

Lymphocytes are not immature T-cells

Diverse differentiation that resembles carcinomas arising anywhere else

Examples: squamous cell carcinoma, basaloid carcinoma, clear cell carcinoma, mucoepidermoid-carcinoma, adenocarcinomas, sarcomatoid, and NUT carcinoma

metastatic squamous cell carcinoma

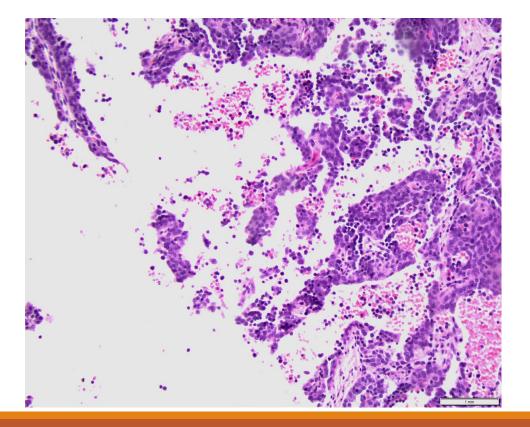

Almost impossible to differentiate a Thymic carcinoma (SQCC) from a SQCC from another site (lung)

CD5 and CD117+ is seen in about 60% of TC, but CD117 can be seen focally in other SQCC

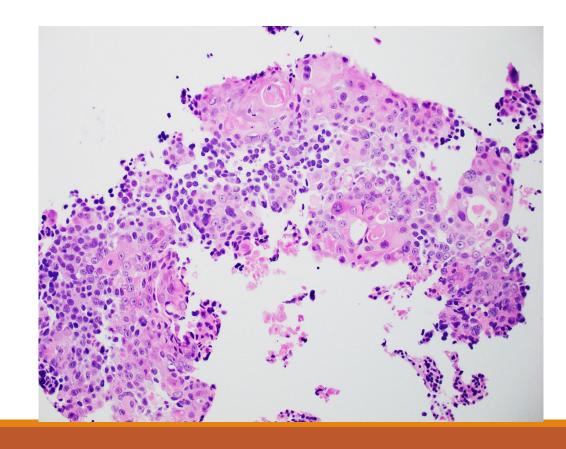

Correlate with history and Imaging studies

Pitfalls

THYMOMA

THYMIC CARCINOMA

Take home message

- Thymomas often metastasizes to the pleura
- •Thymoma should always enter into the differential diagnosis when an anterior mediastinal mass is present.
- •Thymic tumors are positive for p63, p40, and cytokeratins.
- Always look for thymic lymphocytes (TdT, CD99, CD1a positive)

Take home messages for thymoma

Thymomas can have different cytologic patterns, which is similar to histologic classification

There is no need to classify thymomas into subtypes in cytology

Correct diagnosis and disease stage are enough for clinical management

Case 4

22 year old man, non-smoker

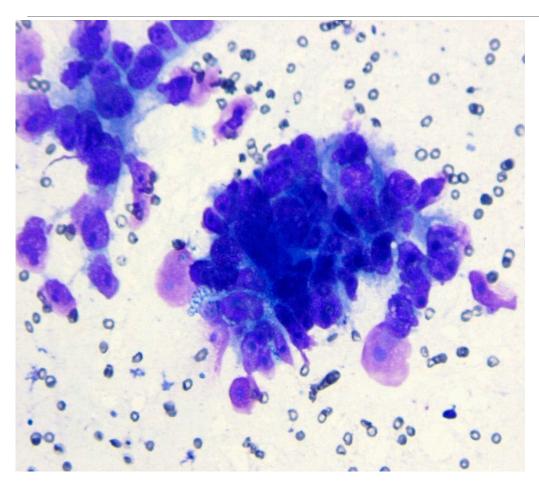

Presented with fever, cough, and malaise

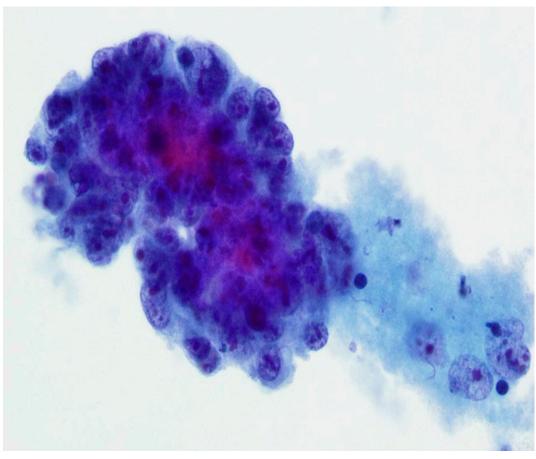

A Chest X-Ray was performed to rule out pneumonia

A large mediastinal mass was found incidentally

An aspiration biopsy of the mass was performed

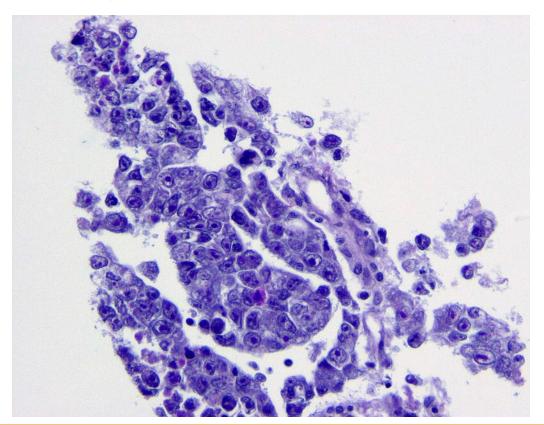

FNA of a mediastinal mass

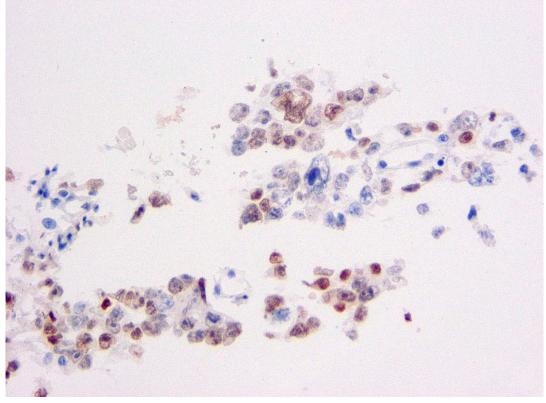

Embryonal carcinoma

CELL BLOCK

POSITIVE FOR OCT 4

Germ Cell Tumors

Rare

Mediastinal germ cell tumors account for less than 5% of all germ cell tumors

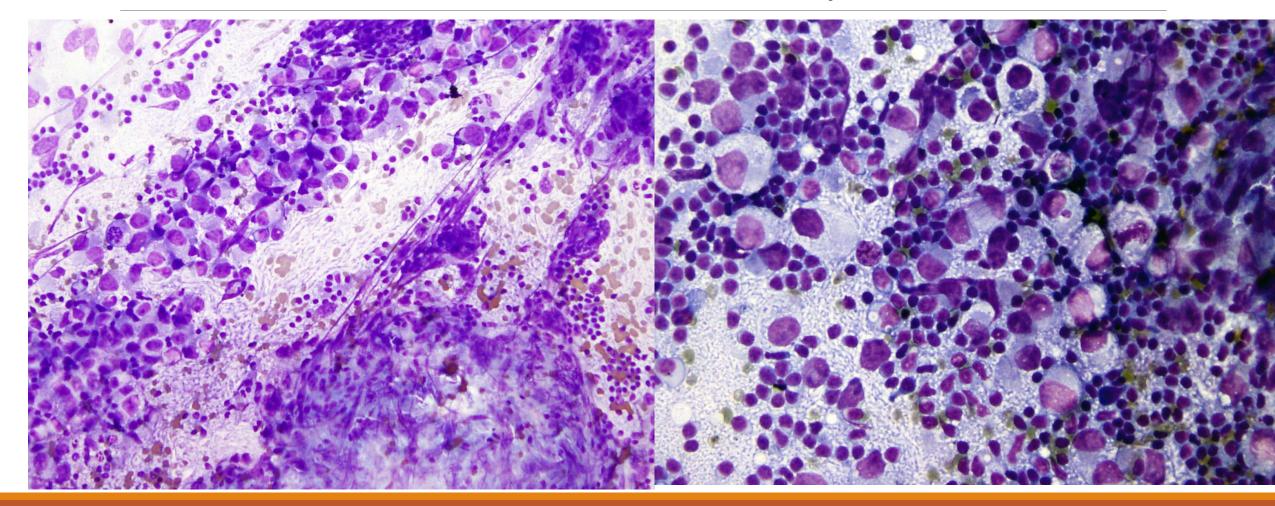

The components of a germ cell tumor is important for the management of the patient

Not all components of a GCT may be sampled in an aspiration biopsy.

There is good correlation with serum markers.

Germ cell tumor	Cytokeratin	OCT4 (OCT3/4)	SALL4	CD117	CD30	AFP	b HCG	Glypican3
type								
Seminoma	Neg*	+	+	+	Neg	Neg	Neg	Neg
Embryonal carcinoma	+	+	+	-/+	+	+/-	Neg	Neg
Yolk sac tumor	+	Neg	+	+/-	Neg	+	Neg	+
Choriocarcinoma	+	Neg	+ (mononuclear trophoblast)	Neg	Neg	Neg	+	+ (syncytiotrophoblast)
	+ (epithelial component)	Neg	-/+ (focal staining in enteric glands; and primitive neuroepithelium and blastema-like stroma of immature teratoma)	-/+	Neg	-/+ ***	Neg	+/-

FNA mediastinal mass in 20 year old man

IHC

Tumor cells are positive for:

SALL 4

D2-40

CD117

Seminoma, mediastinal

Pure seminoma is rare

Often part of a mixed germ cell tumor

Post-pubertal occurrence

40% metastasize to lymph nodes and lung

Histologic diagnosis	Therapeutic option				
Seminoma	Chemotherapy				
Yolk sac tumor	Chemotherapy, followed by resection of remaining tumor mass				
Embryonal carcinoma	Chemotherapy, followed by resection of remaining tumor mass				
Choriocarcinoma	Chemotherapy, followed by resection of remaining tumor mass				
Mixed germ cell tumor	Chemotherapy, followed by resection of remaining tumor mass				
Mature teratoma	Surgical resection				
Immature teratoma	Surgical resection				

Pitfalls for the diagnosis of germ cell tumors

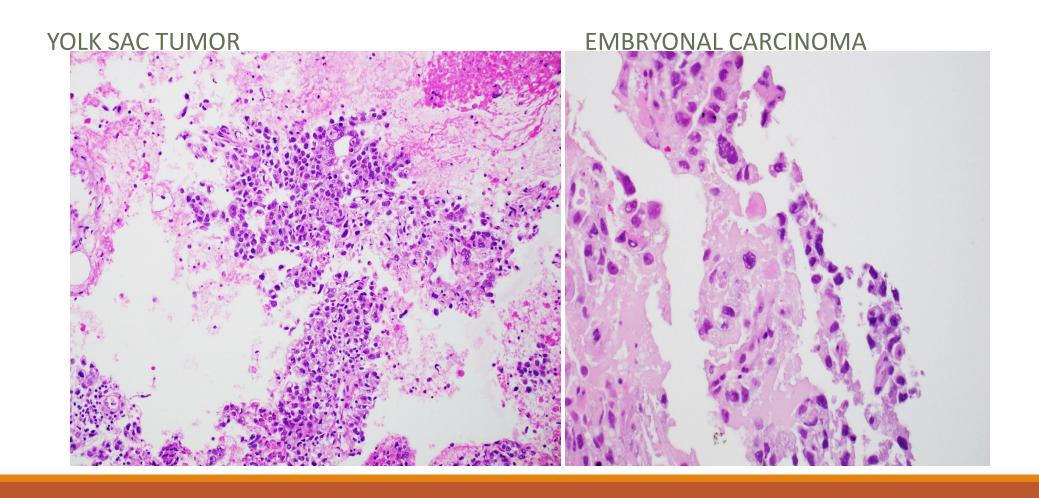

Mix germ cell tumors are more common

Always correlate with serum markers that may indicate another component

Embryonal carcinoma and Yolk Sac tumors mimic high grade carcinomas.

Clinical correlation is very helpful!

Germ cell tumor

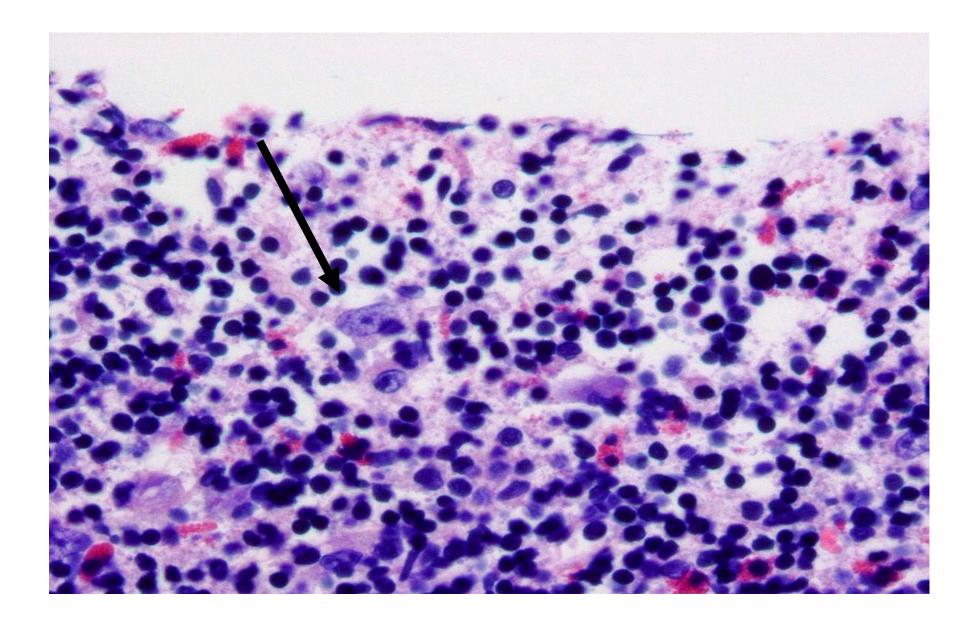

Inflammatory pattern

Hodgkin lymphoma

Sarcoidosis

Other granulomatous inflammation

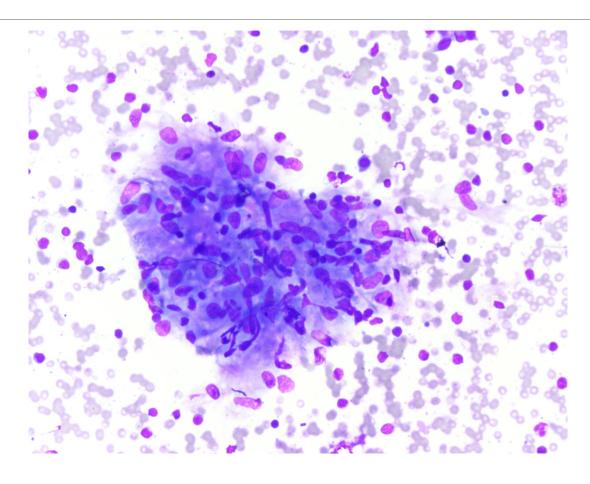

Hodgkin's lymphoma of the mediastinum

Classical Hodgkin's lymphoma is the most common type in the mediastinum

It can arise from the thymus or in mediastinal lymph nodes

The tumor can be associated with cystic changes or thymic hyperplasia

Granulomatous inflammation

granuloma

Infectious

Sarcoidosis

Component of lymphoma (Hodgkin)

Component of germ cell tumor (seminoma)

Small blue cell pattern

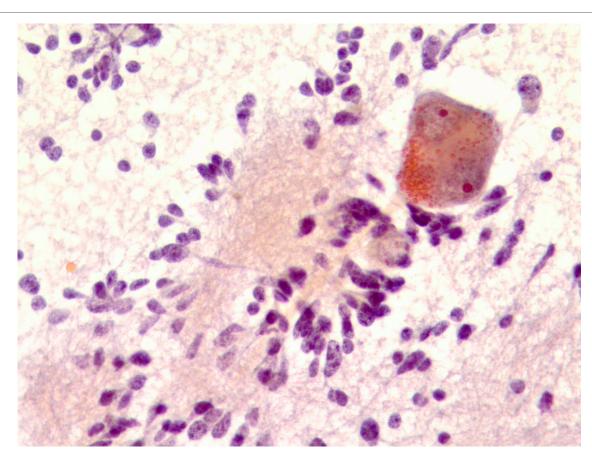

Small cell carcinoma

Ewing sarcoma

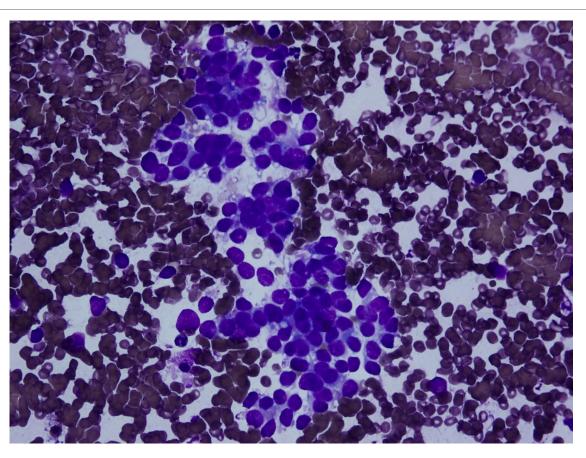

Neuroblastoma

Immature neuroepithelium of teratoma

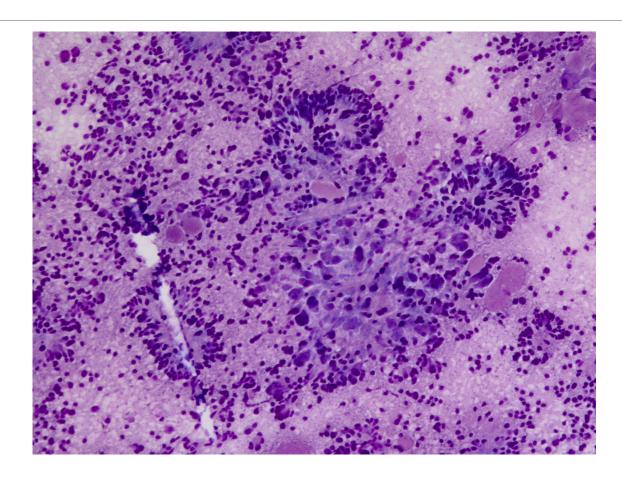

ganglioneuroblastoma

Ewing sarcoma

neuroblastoma

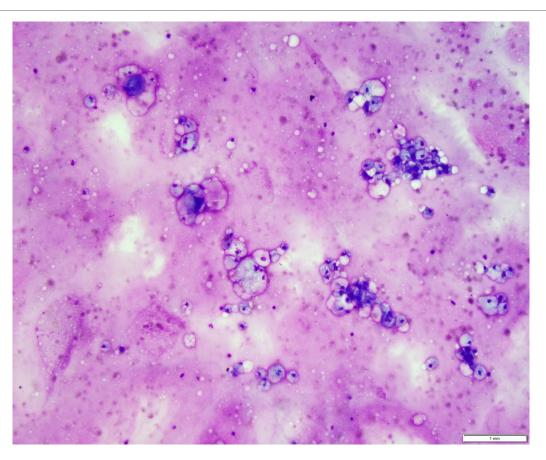

Cystic pattern

Difficult to diagnosis before surgery!

Cystic lesions- thymic cyst, mesothelial cysts, bronchogenic cysts

More likely diagnosed as unsatisfactory or non-diagnostic

Cyst content

Thymic cyst

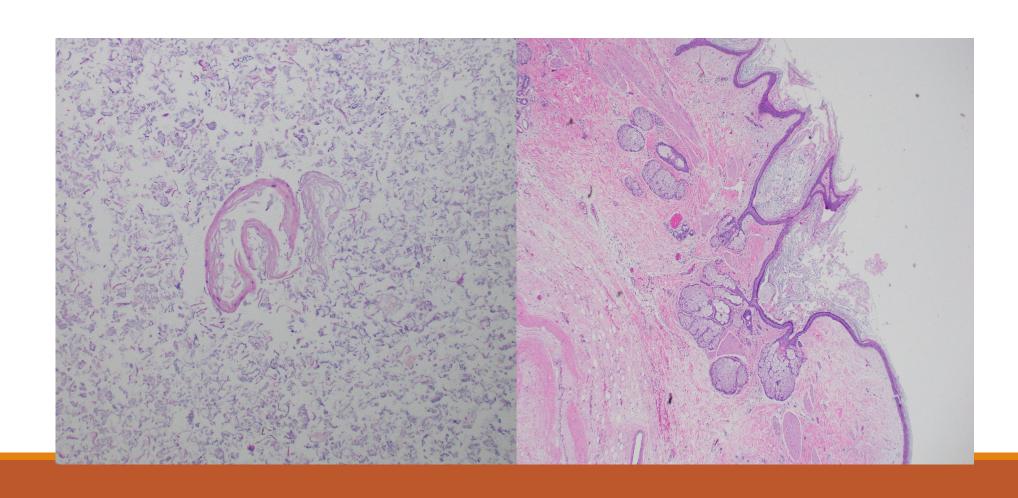

Benign process thought to be acquired or reactive.

Can be lined by cuboidal, flat, squamous or ciliated epithelium

Biopsy is generally not diagnostic, needs radiographic correlation

Often associated with neoplastic process, that are NOT necessarily located within the thymus

teratoma

Thank you!
