Not all Sub-massive PE is created equally.

Case

64-year-old woman with a history of HTN, presented to an OSH ER with complaints of chest pain, dyspnea, and palpitations and episode of syncope

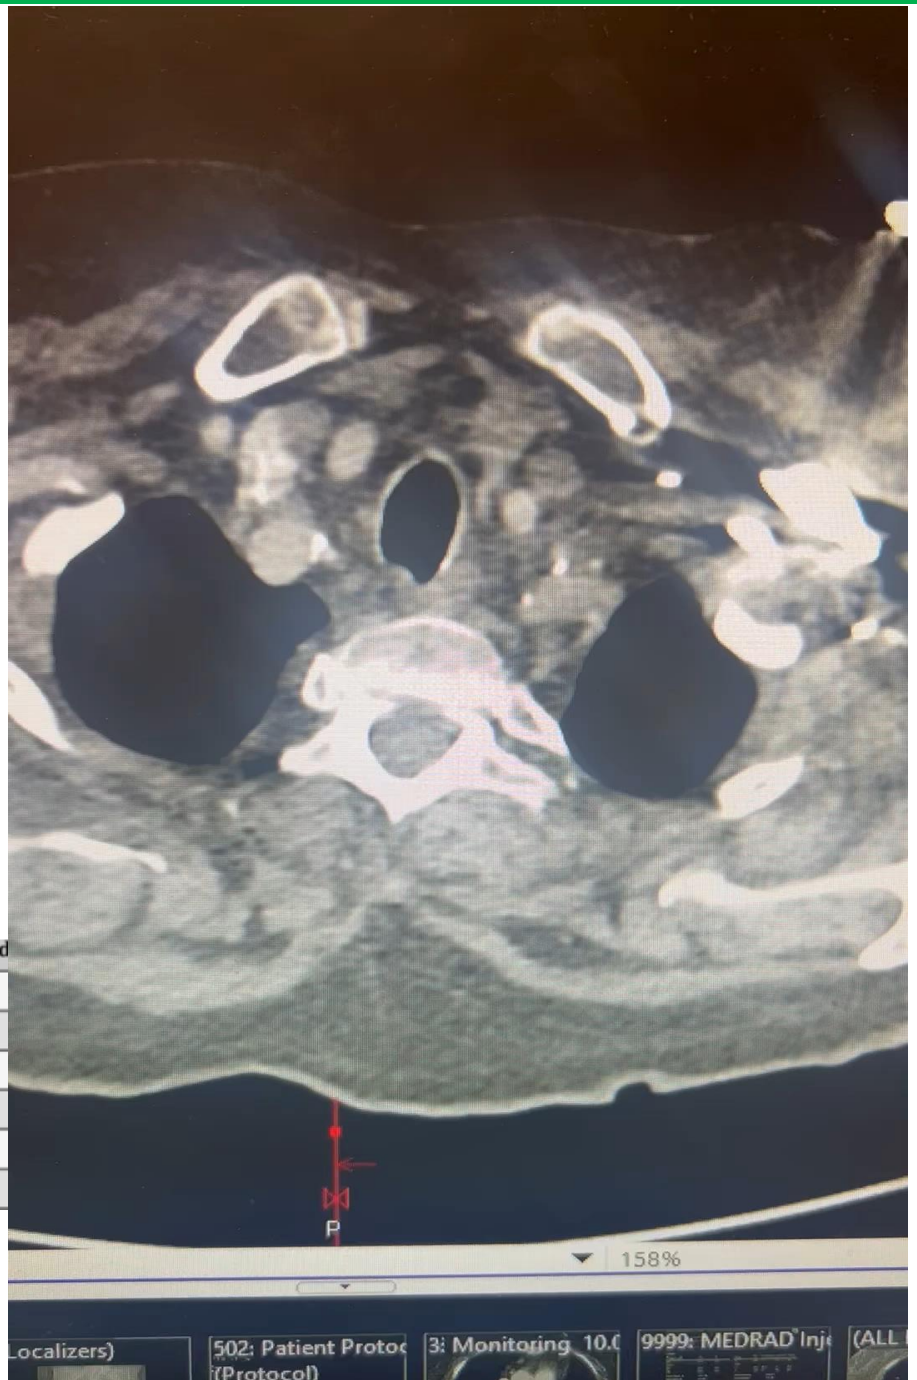
VS in ER: HR 160s, BP 100/80, RR 25, 88% SaO2 on room air.

PERT Patient

Labs

- hsTroponin → 83 → 167 → 149 → 172 (6PM)
- Lactic Acid 3.7
- NT-proBNP 1138

Parameters	Points assigned
Age > 80 years	+1
History of cancer	+1
History of chronic cardiopulmonary disease	+1
Pulse rate ≥ 110/min	+1
Systolic blood pressure < 100 mmHg	+1
Arterial blood oxygen saturation < 90%	+1



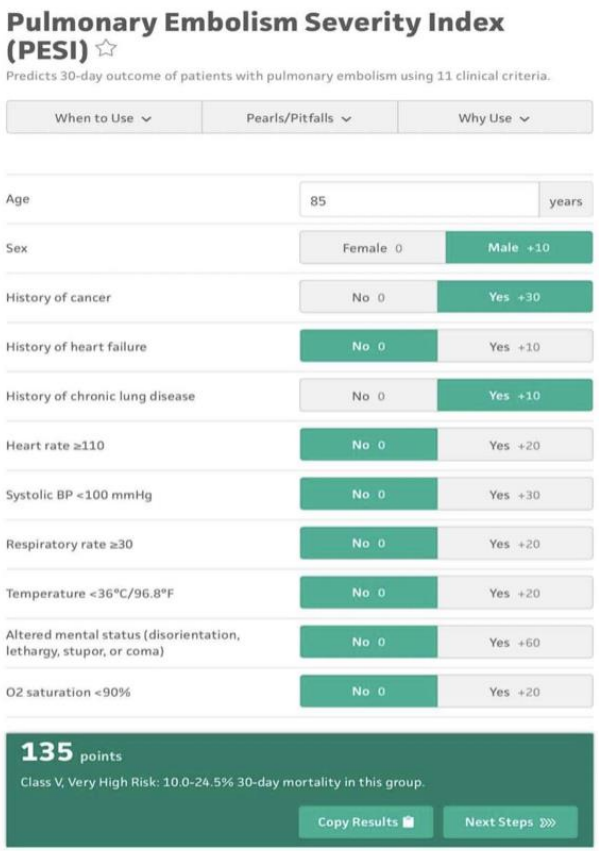
Allegheny Health Network

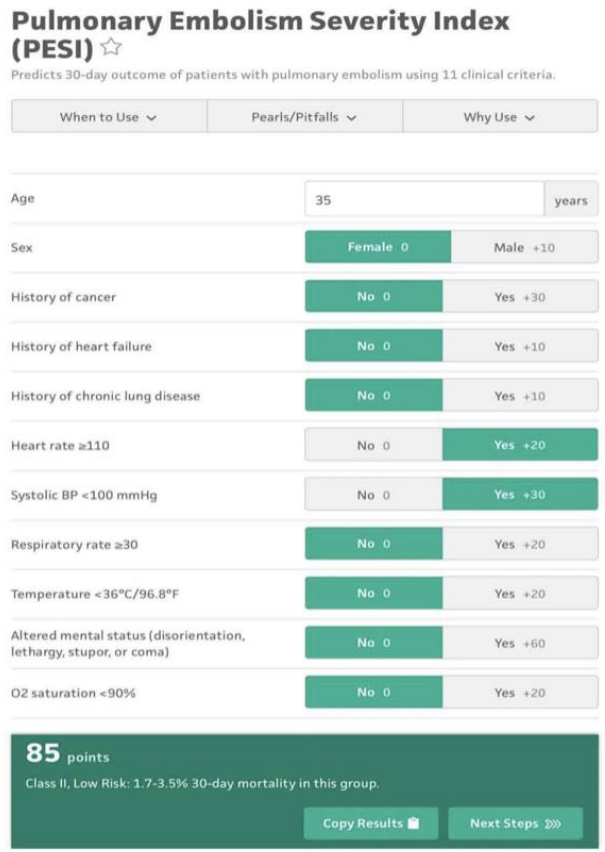
Current Risk Stratification

1. **PESI Score**
   - Designed to predict 30 day all cause mortality.
   - Heavy focus on epidemiological data

2. **BOVA Score**
   - Easy to use
   - Validated for hemodynamically stable patients
   - Does not stratify etiology of instability

Examples of how the PESI score fails in acute prognosis of PE





PESI score fails because it was designed to detect 30-day all-cause mortality (not short-term PE-related mortality).

- **Left panel**: PESI may categorize elderly patients with comorbidities as "very high risk" - even if they have a tiny pulmonary embolism and have no acute physiologic abnormality at all.
- **Right panel**: PESI may categorize young patients without comorbidities as "low risk" - even if they have hemodynamic instability.

Allegheny Health Network

ACC/AHA Guidelines = Way behind

FIGURE 2 Risk Categories for Patients Presenting With Acute PE

Guidelines	Category	Hemodynamic Status	PE Severity Index (PESI) (or Simplified PESI)	Evidence of RV Dysfunction
American Heart Association (AHA, 2011)	Massive	Unstable	High	Typically Abnormal RV on Imaging, Elevated Troponin, OR Both
	Submassive	Stable	High	May Have Abnormal RV on Imaging OR Elevated Troponin OR Both
	Low Risk	Stable	Typically Low	None
European Society of Cardiology (ESC, 2019)	High Risk	Unstable	High	Typically Abnormal RV on Imaging, Elevated Troponin, OR Both
	Intermediate-High Risk	Stable	High	Abnormal RV on Imaging, AND Elevated Troponin
	Intermediate-Low Risk	Stable	High	May Have Abnormal RV on Imaging OR Elevated Troponin But Not Both
	Low Risk	Stable	Low	None

Although terminology may differ, risk stratification strategies are consistent in considering hemodynamics, clinical presentation, and evidence of RV dysfunction.
PESI = Pulmonary Embolism Severity Index; RV = right ventricular.

2020 JACC State of the Art Review: Advanced Management of Intermediate and High-Risk Pulmonary Embolism

Allegheny Health Network

What percentage of PE presentations fall into Massive/Sub-massive category?

TABLE 84.1 Classification of Acute Pulmonary Embolism

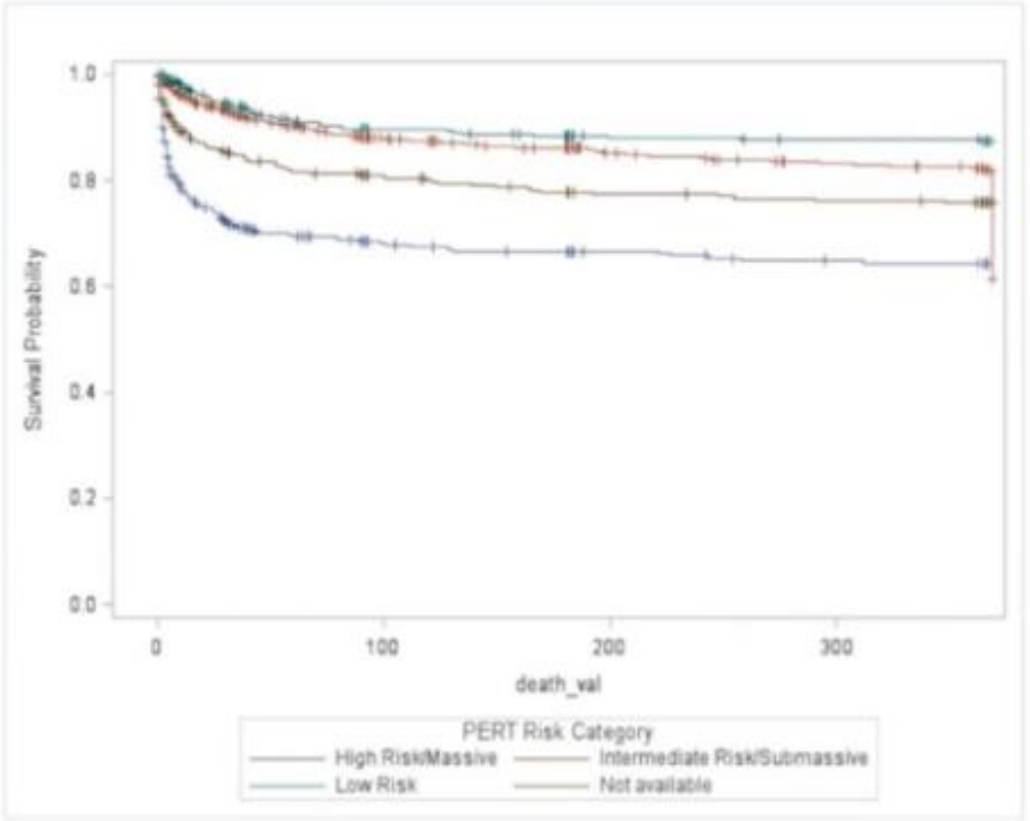
CATEGORY (FREQUENCY)	PRESENTATION	THERAPY
Massive PE (5% to 10%)	Systolic blood pressure < 90mmHg or poor tissue perfusion or multisystem organ failure plus extensive thrombosis, such as "saddle" PE or right or left main pulmonary artery thrombus	Anticoagulation (usually with high-dose intravenous UFH), plus advanced therapy: systemic thrombolysis, pharmacomechanical catheter–directed therapy, surgical embolectomy, and/or inferior vena cava (IVC) filter
Submassive PE, high risk (15%)	Hemodynamically stable but moderate or severe RV dysfunction or enlargement, coupled with biomarker elevation indicative of RV microinfarction and/or RV pressure overload	Anticoagulation until decision made regarding implementation of advanced therapy; controversy centers on this group. For systemic thrombolysis, reducing the rate of cardiovascular collapse and death must be balanced against the increased rate of hemorrhagic stroke.
Submassive PE, low risk (5% to 10%)	Hemodynamically stable with RV dysfunction or biomarker elevation, but not both	Anticoagulation followed by "watch and wait." Implement advanced therapy if there is clinical deterioration.
Small to moderate PE (70%)	Normal hemodynamics and normal RV size and function	Anticoagulation and consider brief hospital stay or entirely home therapy.

RV, right ventricular; *UFH*, unfractionated heparin.

PERT Consortium Data

Survival of PERT PE Patients

	All patients	PERT Risk Category		
		High Risk	Intermediate Risk	Low Risk
30 day mortality	10.2%	27.7%	6.7%	5.2%
1 year mortality	20.1%	35.6%	17.7%	12.5%



Role of Systemic Thrombolytics

1. Thrombolytic therapy in patients with hemodynamic instability (massive PE) is considered standard of care……based on very little RCT data

2. What remains controversial is the use of thrombolytic therapy in patients who are hemodynamically stable at the time of presentation.

Role of Systemic Thrombolytics

In patients who are hemodynamically stable, what does administration of thrombolytics do?

1. Prevent death?

2. Prevent Chronic thromboembolic pulmonary hypertension (CTEPH)?

3. Improve symptoms?

4. Prevent hemodynamic collapse?

Role of Systemic Thrombolytics

Figure 3. Odds of Mortality in Patients With Intermediate-Risk Pulmonary Embolism Treated With Thrombolytic Therapy vs Anticoagulation

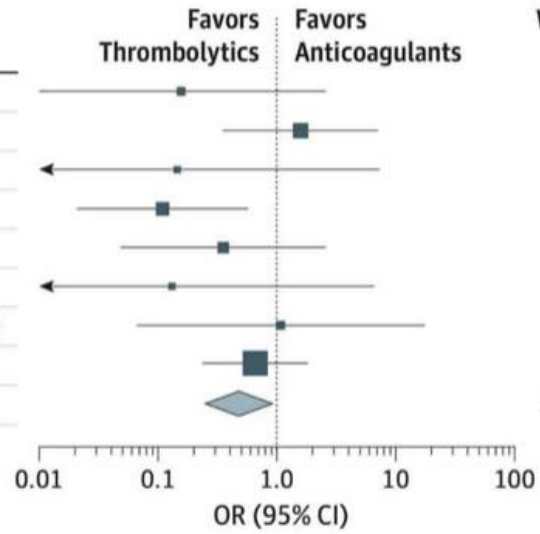
Overall effect: $z = 2.22$; $P = .03$



Meta-analyses disagree about whether thrombolysis improves mortality in sub-massive PE. This analysis in JAMA found a mortality benefit, but other meta-analyses have not (Chatterjee S et al. JAMA 311:2414). *Any* evidence of benefit here (whether or not statistically significant) suggests that benefit exists for patients with *high-risk submassive PE* (because patients in the high-risk subgroup would be expected to have greater benefit than the entire pool of patients with both low-risk submassive PE and high-risk submassive PE).

Konstantinides, S et al. JACC 2016.12.039

ABSTRACT

BACKGROUND The long-term effect of thrombolytic treatment of pulmonary embolism (PE) is unknown.

OBJECTIVES This study investigated the long-term prognosis of patients with intermediate-risk PE and the effect of thrombolytic treatment on the persistence of symptoms or the development of late complications.

METHODS The PEITHO (Pulmonary Embolism Thrombolysis) trial was a randomized (1:1) comparison of thrombolysis with tenecteplase versus placebo in normotensive patients with acute PE, right ventricular (RV) dysfunction on imaging, and a positive cardiac troponin test result. Both treatment arms received standard anticoagulation. Long-term follow-up was included in the third protocol amendment; 28 sites randomizing 709 of the 1,006 patients participated.

RESULTS Long-term (median 37.8 months) survival was assessed in 353 of 359 (98.3%) patients in the thrombolysis arm and in 343 of 350 (98.0%) in the placebo arm. Overall mortality rates were 20.3% and 18.0%, respectively ($p = 0.43$). Between day 30 and long-term follow-up, 65 deaths occurred in the thrombolysis arm and 53 occurred in the placebo arm. At follow-up examination of survivors, persistent dyspnea (mostly mild) or functional limitation was reported by 36.0% versus 30.1% of the patients ($p = 0.23$). Echocardiography (performed in 144 and 146 patients randomized to thrombolysis and placebo, respectively) did not reveal significant differences in residual pulmonary hypertension or RV dysfunction. Chronic thromboembolic pulmonary hypertension (CTEPH) was confirmed in 4 (2.1%) versus 6 (3.2%) cases ($p = 0.79$).

CONCLUSIONS Approximately 33% of patients report some degree of persistent functional limitation after intermediate-risk PE, but CTEPH is infrequent. Thrombolytic treatment did not affect long-term mortality rates, and it did not appear to reduce residual dyspnea or RV dysfunction in these patients. (Pulmonary Embolism Thrombolysis study [PEITHO]; NCT00639743) (J Am Coll Cardiol 2017;69:1536–44) © 2017 by the American College of Cardiology Foundation.

Thrombolytics Not Used in Most Unstable PE Patients

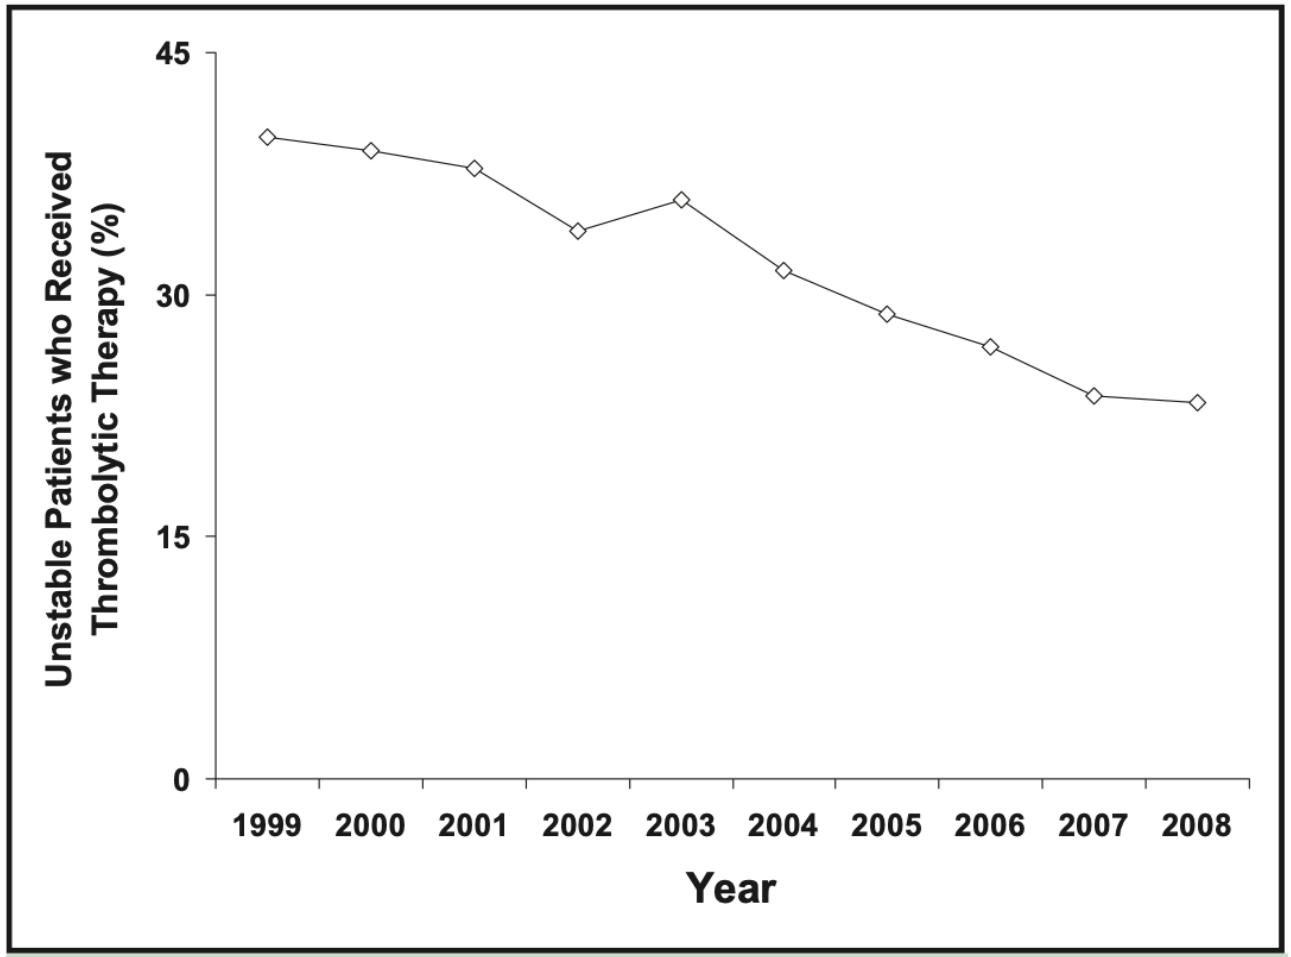

Figure 1 Proportion of unstable patients with pulmonary embolism who received thrombolytic therapy. The proportion decreased linearly from 1999 to 2008 ($r = -0.9797$, slope -1.1998 %/year, $P < .0001$).

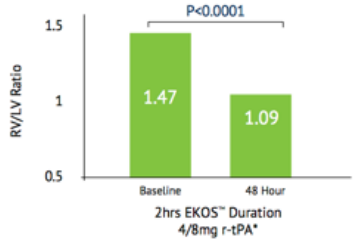
sis for acute PE improves
angiographic obstruction.
potential "game-changer"
nts.

OPTALYZE PE: EKOS 4 Cohorts
(n= 101; 17 centers across US)

Acute PE patients treated with EKOS™ showed the following improvements:

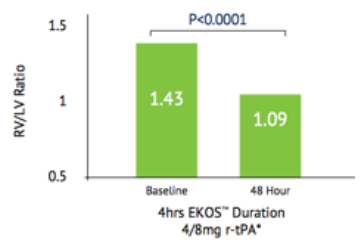
- **Significant reduction in RV/LV ratios in all cohorts at 48 hours post initiation of procedure**
- **RV/LV ratio reduced by 24% (P<0.0001) for the two-hour cohort using only 4mg of r-tPA per catheter**
- **All cohorts had zero to very low bleeding rates[1]**

Cohort 1
24% Reduction in RV/LV Ratio



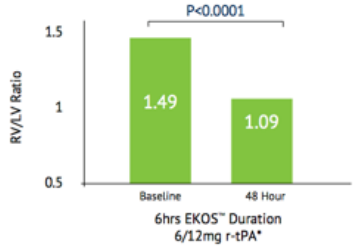
2hrs EKOS™ Duration
4/8mg r-tPA*

Cohort 2
23% Reduction in RV/LV Ratio



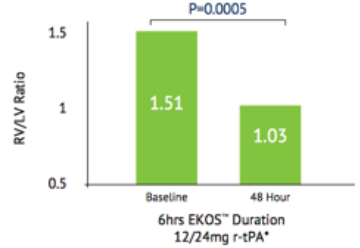
4hrs EKOS™ Duration
4/8mg r-tPA*

Cohort 3
26% Reduction in RV/LV Ratio



6hrs EKOS™ Duration
6/12mg r-tPA*

Cohort 4
26% Reduction in RV/LV Ratio



6hrs EKOS™ Duration
12/24mg r-tPA*

CONCLUSION

The EKOS™ system's very-low-dose and short-duration regimens in the OPTALYSE PE trial appear to be as acutely effective as the regimens in other EKOS™ studies (ULTIMA & SEATTLE II), pointing to a paradigm-changing approach for PE treatment. These results offer physicians a new treatment standard for proven PE clinical efficacy and safety.

	CDT N = 276	LBMT N = 274	*P* value
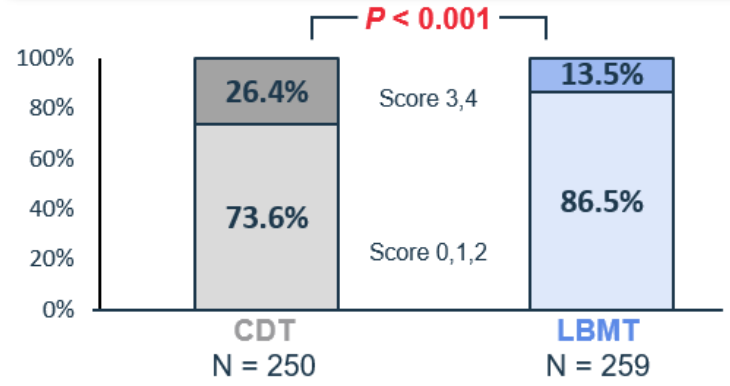
Clinical deterioration and/or escalation to bailout	**15 (5.4)**	**5 (1.8)**	**0.038**
Patients with clinical deterioration	10 (3.6)	4 (1.5)	
Cardiac arrest	2 (0.7)	0 (0.0)	
High-grade atrioventricular block	1 (0.4)	0 (0.0)	
Respiratory failure	3 (1.1)	0 (0.0)	
Increased oxygen requirement	0 (0.0)	1 (0.4)	
Hypotension	4 (1.4)	3 (1.1)	
Patients with escalation to bailout	6 (2.2)	1 (0.4)	
Successful bailout†	5 (1.8)	0 (0.0)	
Unsuccessful bailout‡	1 (0.4)	1 (0.4)	

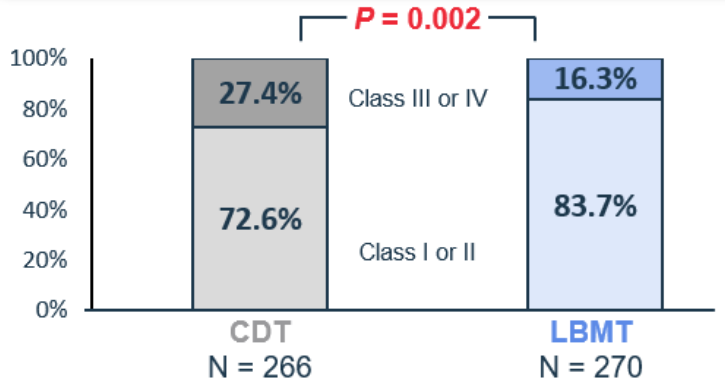
Values reported as n (%). *P* value calculated using two-sided Fisher's exact test. Bailout: N=275 CDT. †5 CDT patients underwent LBMT bailout procedure without adverse event, experienced postprocedural improvement, and were discharged without further intervention. ‡1 patient in each arm had a PE that could not be treated after multiple bailout attempts (systemic tPA, LBMT, CDT) and ultimately died after >7 days.

Clinical and imaging outcomes at 24-hour visit

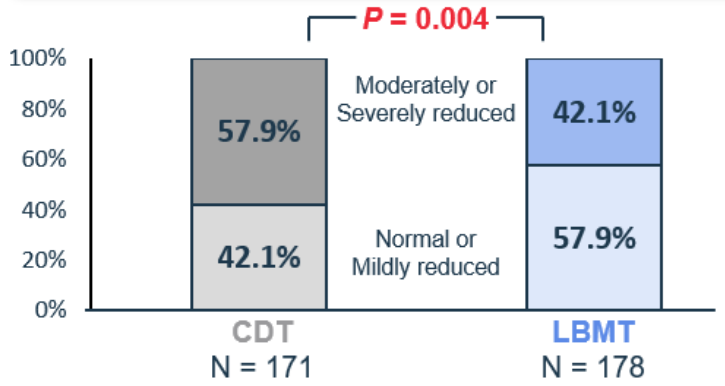
mMRC dyspnea score



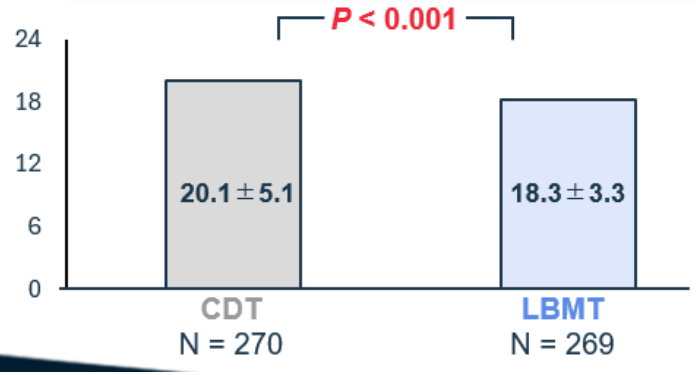
NYHA classification



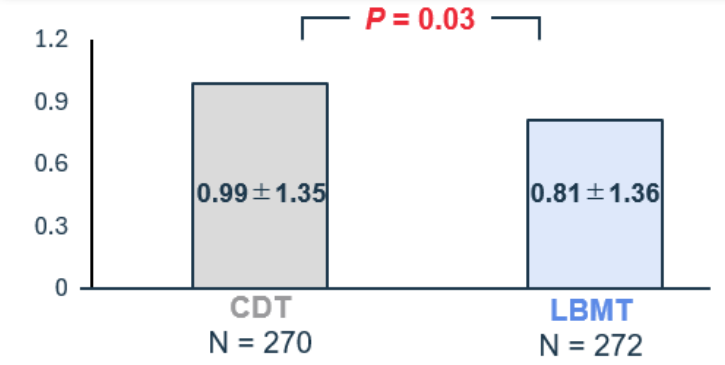
RV function (echo)



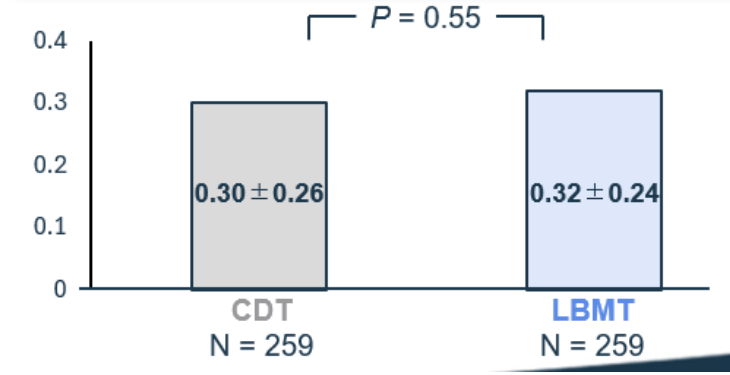
Respiratory rate (breaths/min)



Modified Borg dyspnea score at rest



Reduction in RV/LV ratio from baseline



Hospital length of stay and 30-day readmissions

	CDT N = 276	LBMT N = 274	*P* value
Total hospital LOS, days	5.3 ± 3.9	4.5 ± 2.8	**0.002**
Postprocedure LOS, days	4.0 ± 3.7	3.2 ± 2.7	**< 0.001**
Postprocedure ICU admission	272 (98.6)	114 (41.6)	**< 0.001**
stay ≤ 24 hours	94 (34.1)	61 (22.3)	**< 0.001**
stay > 24 hours	178 (64.5)	53 (19.3)	
Postprocedure ICU LOS, hours	39.3 ± 28.0	14.2 ± 25.4	**< 0.001**
30-day all-cause readmission†	19 (7.9)	8 (3.2)	**0.03**
30-day PE-related readmission†	2 (0.8)	0 (0.0)	0.237

Values reported as n (%) or mean ± SD. †30-day readmission: N=239 CDT, N=251 LBMT. Total and postprocedure hospital stay reported through 30 days. Postprocedure ICU stay reported through discharge / 7 days. *P* values calculated using two-sided Fisher's exact test or two-sided Wilcoxon rank sum test with continuity correction.

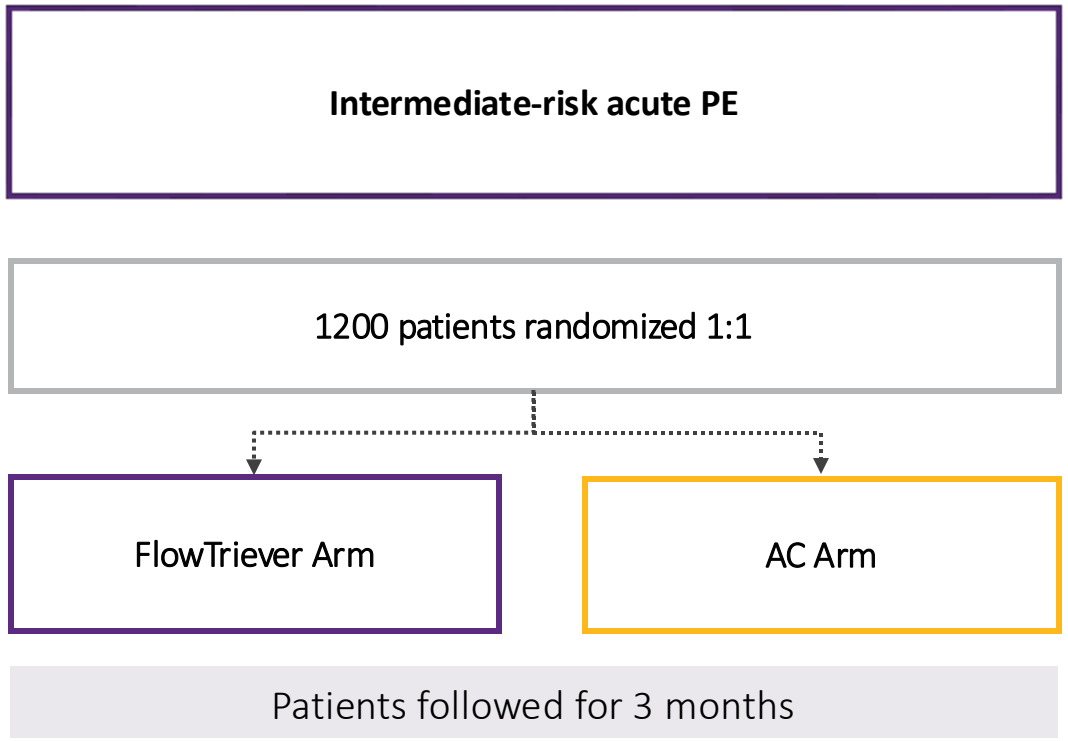
Conclusions

- PEERLESS met its primary endpoint, demonstrating superiority of LBMT compared to CDT in the treatment of acute intermediate-risk PE
- There was no difference between groups in:
  - mortality (very low in both arms), ICH, or major bleeding
- Compared to CDT, LBMT was associated with:
  - Less clinical deterioration or escalation of therapy
  - Faster clinical and hemodynamic improvement at 24 hours
  - Less ICU use and shorter hospital length of stay
  - Fewer readmissions through 30 days

PEERLESS II: RCT of FlowTriever vs. anticoagulation alone in acute PE

PEERLESS II

RCT of FlowTriever vs. anticoagulation alone in pulmonary embolism



Designed to evaluate whether anticoagulation alone or large-bore volume-controlled aspiration thrombectomy should be standard of care for intermediate-risk PE

Primary endpoint hierarchy (win ratio):

- All-cause mortality by 30 days
- Clinical deterioration and/or bailout by 30 days
- All-cause hospital readmission by 30 days
- Dyspnea score at 48-hour visit

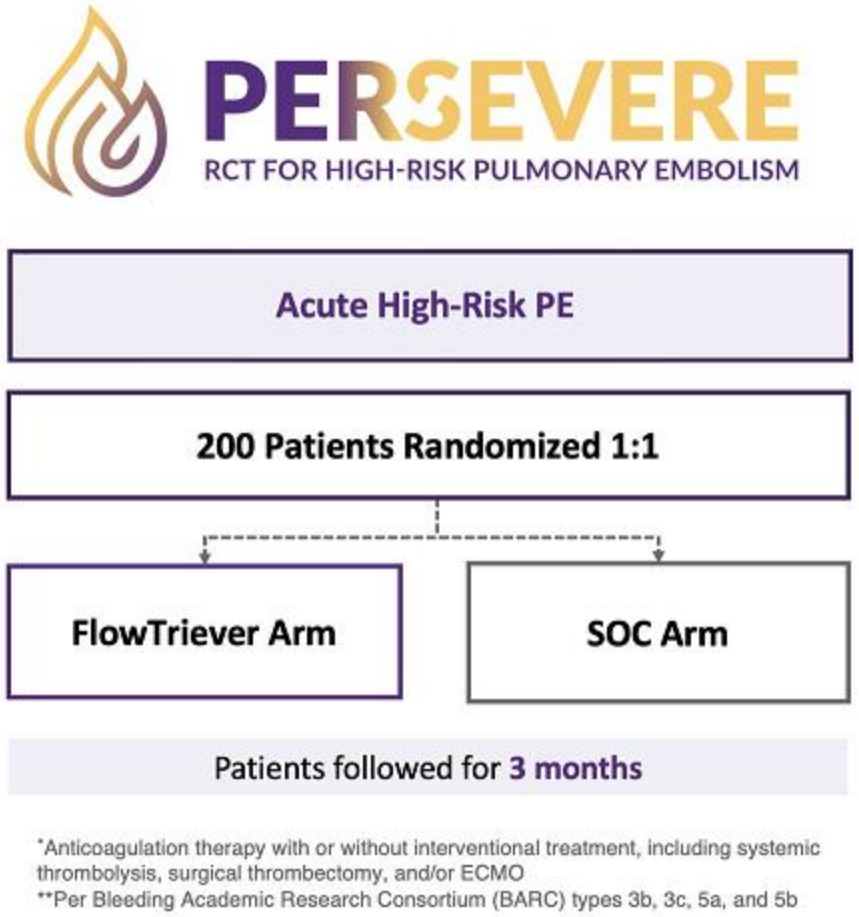
Indications for Use: The FlowTriever Retrieval/Aspiration system is indicated for (1) the non-surgical removal of emboli and thrombi from blood vessels; and (2) the injection, infusion, and/or aspiration of contrast media and other fluids into or from a blood vessel. The FlowTriever Retrieval/Aspiration system is intended for use in the peripheral vasculature and for the treatment of pulmonary embolism. The Triever catheters are also intended for use in treating clot in transit in the right atrium, but not in conjunction with FlowTriever catheters. Refer to IFU for complete indications for use, contraindications, warnings, and precautions. Caution: Federal (USA) law restricts this device to sale distribution and use by or on order of a physician.

Finally, some RCT data in High-Risk PE!



Designed to evaluate whether large-bore volume-controlled mechanical thrombectomy vs SOC* should be the guideline-recommended first-line therapy for high-risk PE

Composite Primary Endpoint

Through the earlier of initial hospital discharge or 7 days:

- All-cause mortality
- Cardiac arrest with loss of consciousness requiring CPR
- Bailout to an alternate therapeutic strategy
- Major bleeding**
- Persistent need for ECMO

Thank you
